< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

## Setting

Let  $(X, d, \mu)$  be a metric measure space. When  $E \subset X$  and t > 0, we denote

$$E_t = \{x \in X : \mathsf{dist}(x, E) < t\}$$

and call  $E_t$  the *(open)* t-neighborhood of E. Our main purpose is to study the *p*-capacities cap<sub>p</sub>( $E, E_t$ ) of a compact set E as t varies (especially when  $t \rightarrow 0$ ).

Here

$$\mathsf{cap}_p(E,\Omega) = \inf \Big\{ \int_\Omega |Du|^p \, d\mu : 0 \le u \in \mathsf{Lip}_0(\Omega), \, \, u = 1 \, \, \mathsf{in} \, \, E \Big\}$$

for  $\Omega \subset X$  open and  $E \subset \Omega$  compact,  $\operatorname{Lip}_0(\Omega)$  is the set of compactly supported Lipschitz-functions in  $\Omega$ , and the function Du is a 'suitable gradient' of  $u \in \operatorname{Lip}_0(\Omega)$  (in  $\mathbb{R}^n$  we have  $Du = \nabla u$ ).

# Sets of non-zero capacity

A compact set  $E \subset X$  is of zero capacity,  $\operatorname{cap}_p(E) = 0$ , if  $\operatorname{cap}_p(E, \Omega) = 0$ for all open sets  $\Omega \supset E$ ; otherwise we write  $\operatorname{cap}_p(E) > 0$ .

It is immediate that  $cap_p(E) = 0$  if and only if  $cap_p(E, E_t) = 0$  for all 0 < t < diam(E).

For sets of non-zero capacity (in  $\mathbb{R}^n$ ) we have the following result by Väisälä:

Theorem (Väisälä (MMJ, 1975)) Let  $1 . If <math>E \subset \mathbb{R}^n$  is a compact set with  $\operatorname{cap}_p(E) > 0$ , then  $\operatorname{cap}_p(E, E_t) \to \infty$  as  $t \to 0$ .

(The same actually holds in a 'reasonable' metric space setting as well)

◆□ → ◆□ → ◆三 → ◆三 → □ □ □

### More history

We also have the following results for the *n*-capacity in  $\mathbb{R}^n$ :

### Theorem (Vuorinen (CGAQRM, 1985))

If  $E \subset \mathbb{R}^n$  is a compact set, then  $\operatorname{cap}_n(E, E_t) \leq Ct^{-n}$  for every  $0 < t < \operatorname{diam}(E)$ . Moreover,  $t^{-n}$  is the best asymptotics that one can have for a general set.

### Theorem (Heikkala (AASCFD, 2002))

If  $E \subset \mathbb{R}^n$  is a compact  $\lambda$ -Ahlfors regular set for  $0 \le \lambda < n$ , then  $\operatorname{cap}_n(E, E_t) \approx t^{-\lambda}$  for every  $0 < t < \operatorname{diam}(E)$ .

These results were obtained using modulus estimates. Porosity of *E* was assumed in the lower bound, but this follows from the  $\lambda$ -regularity for  $\lambda < n$ .

# A result for *p*-capacity

It is now natural to ask how  $\operatorname{cap}_p(E, E_t)$  behaves, when (e.g.) E is  $\lambda$ -regular.

Theorem (L. 2010)

Let  $1 and <math>0 \le \lambda < n$ , and assume that  $E \subset \mathbb{R}^n$  is an Ahlfors  $\lambda$ -regular compact set. If  $p > n - \lambda$ , then

$$\operatorname{cap}_p(E, E_t) \approx t^{n-\lambda-p}$$

for all 0 < t < diam(E), and if  $p \le n - \lambda$ , then  $cap_p(E, E_t) = 0$  for all t > 0.

This result follows from more general upper and lower bounds that we establish separately with weaker assumptions; these results hold in general metric spaces as well.

#### 2. Preliminaries

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

### Metric spaces

We assume that  $X = (X, d, \mu)$  is a metric mesure space satisfying the following (standard) assumptions:

- measure  $\mu$  is *doubling*:  $\mu(2B) \leq C_d \mu(B)$  for each ball  $B \subset X$
- X supports a (weak) p-Poincaré inequality:

$$\int_{B} |u - u_{B}| \, d\mu \leq Cr \Big( \int_{\tau B} g_{u}^{p} \, d\mu \Big)^{1/p}$$

whenever  $u \in L^1_{loc}(X)$  and  $g_u$  is an (or a weak) upper gradient of u: For all (or p-almost all) curves  $\gamma$  joining  $x, y \in X$ 

$$|u(x) - u(y)| \le \int_{\gamma} g_u \, ds. \tag{1}$$

For instance, if  $u \in Lip(\Omega)$ , then (1) holds with

$$g_u(x) = \operatorname{Lip}(u; x) = \limsup_{y \to x} \frac{|u(x) - u(y)|}{d(x, y)}$$

### Metric spaces II

If  $\mu$  is doubling, then there exists a number 0  $\leq s < \infty$  such that

$$\frac{\mu(B(y,r))}{\mu(B(x,R))} \ge C\left(\frac{r}{R}\right)^{s}$$
(2)

whenever  $0 < r \le R < \text{diam } X$  and  $y \in B(x, R)$ ; this holds certainly for  $s = \log_2 C_d$ .

In the following we fix some s for which (2) holds, and call this the *doubling dimension* of X.

Measure  $\mu$  is called *(Ahlfors) s-regular*, if  $\mu(B(x, r)) \approx r^s$  for every  $x \in X$  and 0 < r < diam(X).

More generally, a set  $E \subset X$  is said to be (Ahlfors)  $\lambda$ -regular if

$$\mathcal{H}^{\lambda}(E \cap B(x,r)) \approx r^{\lambda}$$

whenever  $x \in E$  and 0 < r < diam(E). (Here  $\mathcal{H}^{\lambda}$  is the usual Hausdorff measure  $\rightarrow$ )

Juha Lehrbäck (University of Jyväskylä)

# Hausdorff and Minkowski

We define the Hausdorff and Minkowski contents of dimension  $\lambda$  as

$$\mathcal{H}_r^{\lambda}(E) = \inf \bigg\{ \sum_k r_k^{\lambda} : E \subset \bigcup_k B(x_k, r_k), \ x_k \in E, \ 0 < r_k \leq r \bigg\},$$

and

$$\mathcal{M}_r^{\lambda}(E) = \inf \left\{ Nr^{\lambda} : E \subset \bigcup_{k=1}^N B(x_k, r), \ x_i \in E \right\},$$

respectively.

It is immediate that  $\mathcal{H}^\lambda_r(E) \leq \mathcal{M}^\lambda_r(E)$  for each compact  $E \subset X$ .

The  $\lambda$ -Hausdorff measure of E is  $\mathcal{H}^{\lambda}(E) = \lim_{r \to 0} \mathcal{H}^{\lambda}_{r}(E)$ .

### Dimensions

The Hausdorff dimension of  $E \subset X$  is

$$\dim_{\mathcal{H}}(A) = \inf\{\lambda > 0: \mathcal{H}^{\lambda}(A) = 0\}$$

The lower and upper Minkowski dimension of  $E \subset X$  are defined to be

$$\underline{\dim}_{\mathcal{M}}(E) = \inf \left\{ \lambda > 0 : \liminf_{r \to 0} \mathcal{M}_r^{\lambda}(E) = 0 \right\}$$

and

$$\overline{\dim}_{\mathcal{M}}(E) = \inf \Big\{ \lambda > 0 : \limsup_{r \to 0} \mathcal{M}_r^{\lambda}(E) = 0 \Big\},$$

respectively.

Notice that for each compact set  $E \subset X$  we have

$$\dim_{\mathcal{H}}(E) \leq \underline{\dim}_{\mathcal{M}}(E) \leq \overline{\dim}_{\mathcal{M}}(E),$$

where all inequalities can be strict. If  $\underline{\dim}_{\mathcal{M}}(E) = \overline{\dim}_{\mathcal{M}}(E)$ , we simply write  $\dim_{\mathcal{M}}(E) = \overline{\dim}_{\mathcal{M}}(E)$ .

In general metric spaces it is often convenient to use modified versions of  $\mathcal{H}_r^{\lambda}$  and  $\mathcal{M}_r^{\lambda}$ , namely the following Hausdorff and Minkowski contents of codimension q:

$$\widetilde{\mathcal{H}}_r^q(E) = \inf \bigg\{ \sum_k \mu(B_k) \, r_k^{-q} : E \subset \bigcup_k B_k, \ x_k \in E, \ 0 < r_k \le r \bigg\},\$$

where we write  $B_k = B(x_k, r_k)$ , and

$$\widetilde{\mathcal{M}}_r^q(E) = \inf \bigg\{ r^{-q} \sum_k \mu(B(x_k, r)) : E \subset \bigcup_k B(x_k, r), \ x_k \in E \bigg\}.$$

Note that in a s-regular space  $\widetilde{\mathcal{H}}_r^q \approx \mathcal{H}_r^{s-q}$  and  $\widetilde{\mathcal{M}}_r^q \approx \mathcal{M}_r^{s-q}$ .

A set  $E \subset X$  is  $\alpha$ -porous (for  $0 < \alpha < 1$ ), if for every  $w \in E$  and all 0 < r < diam(E) there exists a point  $y \in X$  such that

$$B(y, \alpha r) \subset B(w, r) \cap (X \setminus E).$$

It is well-known that in an *s*-regular metric space X a set  $E \subset X$  is porous if and only if the Assouad dimension  $\dim_{\mathcal{A}}(E) < s$ .

Recall that for a  $\lambda$ -regular set  $E \subset X$  we have  $\dim_{\mathcal{H}}(E) = \dim_{\mathcal{A}}(E) = \lambda$ .

### 3. Upper bounds

æ

<ロ> <同> <同> < 同> < 同>

# A general upper bound

#### Lemma

Let  $1 \le p < \infty$ . Then there exists a constant C = C(X, p) > 0 such that

$$\operatorname{cap}_p(E, E_t) \leq C \widetilde{\mathcal{M}}_{t/3}^q(E) t^{q-p}$$

whenever  $E \subset X$  is a compact set and 0 < r < diam(E).

**Idea**: Cover *E* with balls  $B_i = B(w_i, t/3)$ ,  $w_i \in E$ , i = 1, ..., N, and define

$$u(x) = \max_{1 \le i \le N} \{0, 1 - 2t^{-1} \operatorname{dist}(x, B_i)\}.$$

Then  $u \in \text{Lip}_0(E_t)$ , u = 1 in E, and u has an upper gradient  $g_u$  such that

$$g_u(x)^p \leq \sum_{i=1}^N (t/2)^{-p} \chi_{2B_i}(x)$$
 for a.e.  $x \in E_t$  ...

Juha Lehrbäck (University of Jyväskylä)

▲口▶ ▲掃▶ ▲ヨ▶ ▲ヨ▶ ヨー のなべ

A general upper bound, cont'd..

$$\ldots g_u(x)^p \leq \sum_{i=1}^N (t/2)^{-p} \chi_{2B_i}(x)$$
 for a.e.  $x \in E_t$ 

Thus, by the doubling condition,

$${
m cap}_p(E,E_t) \leq \int_{E_t} g_u^p \, d\mu \leq \sum_{i=1}^N (t/2)^{-p} \mu(2B_i) \leq C(t/3)^{-p} \sum_{i=1}^N \mu(B_i).$$

Taking the infimum over all such covers yields the claim

$$\operatorname{cap}_p(E, E_t) \leq C \widetilde{\mathcal{M}}_{t/3}^p(E) = C \widetilde{\mathcal{M}}_{t/3}^q(E) t^{q-p}$$

(the second equality holds for all q)

Notice that no Poincaré inequalities are needed here.

Juha Lehrbäck (University of Jyväskylä)

Neighborhood capacities

### Upper bound under bounded volume growth

As a simple corollary of the previous result we obtain:

#### Lemma

Let  $1 \le p < \infty$  and assume that  $\mu(B(w, r)) \le cr^d$  whenever  $w \in E$  and 0 < r < diam(E). Then there exists a constant C = C(X, p, c) > 0 such that

$$\mathsf{cap}_p(E,E_t) \leq C\mathcal{M}^\lambda_{t/3}(E) t^{d-\lambda-p}$$

for all  $0 < r < \operatorname{diam}(E)$ .

**Idea**: If  $\mu(B(w, r)) \leq cr^d$  for all  $w \in E$  and r < diam(E), we have  $\widetilde{\mathcal{M}}_r^q(E) \leq c\mathcal{M}_r^{d-q}(E)$  for all 0 < r < diam(E). Thus the previous lemma with  $q = d - \lambda$  gives

$$\mathsf{cap}_p(E,E_t) \leq C \widetilde{\mathcal{M}}^q_{t/3}(E) t^{q-p} \leq C \mathcal{M}^\lambda_{t/3}(E) t^{d-\lambda-p}$$

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ● ● ● ● ● ●

# In particular...

### Proposition

(a) Let  $1 \le p < \infty$  and assume that  $E \subset X$  is a compact set satisfying  $\limsup_{r\to 0} \widetilde{\mathcal{M}}_r^q(E) < \infty$ . Then there exists a constant C = C(X, E, p, q) > 0 such that

$$\operatorname{cap}_p(E,E_t) \leq Ct^{q-p}$$

for all 0 < t < diam(E). (b) If  $E \subset X$  is a compact set satisfying  $\limsup_{r\to 0} \mathcal{M}_r^{\lambda}(E) < \infty$ , and if in addition  $\mu(B(w, r)) \leq cr^d$  whenever  $w \in E$  and 0 < r < diam(E), then there exists a constant  $C = C(X, E, p, d, \lambda, c) > 0$  such that

$$\operatorname{cap}_p(E, E_t) \leq Ct^{d-\lambda-p}$$

for all  $0 < t < \operatorname{diam}(E)$ . This is true, in particular, if  $\lambda > \overline{\operatorname{dim}}_{\mathcal{M}}(E)$ .

イロト イポト イヨト イヨト 二日

#### 4. Lower bounds

Juha Lehrbäck	(University of Jyväskylä)	Neighborhood capacities
---------------	---------------------------	-------------------------

- 2

Our lower bounds for neighborhood capacities follow from the next general lemma:

#### Lemma

Let  $1 \le p < \infty$  and let  $E \subset X$  be a compact  $\alpha$ -porous set. Assume that the (1, p)-Poincaré inequality is valid for all balls B(w, r) with  $w \in E$  and 0 < r < diam(E), and let q < p. Then there exists a constant C = C(X, E, p, q) > 0 such that

$$\mathsf{cap}_p(E,E_t) \geq C\widetilde{\mathcal{H}}^q_{10 aulpha^{-1}t}(E)t^{q-p}$$

for all  $0 < t < \operatorname{diam}(E)$ .

(Here  $\tau \geq 1$  is the dilatation constant from the weak Poincaré inequality.)

### Idea of the proof I

Take q < p and let 0 < t < diam(E). Fix  $w \in E$  and define  $r_k = 2^{1-k}\alpha^{-1}t$ ,  $B_k = B(w, r_k)$ . Let  $u \ge 0$  be a test function for the capacity  $\operatorname{cap}_p(E, E_t)$ . From the  $\alpha$ -porosity it follows that u = 0 in  $\tilde{B} = B(y, t)$  for some  $y \in B_0$ . Hence, using doubling,

$$egin{aligned} |u_{B_0}| &= \mu(B_0)^{-1} \int_{B_0 \setminus ilde{B}} u \leq 1 - rac{\mu(B)}{\mu(B_0)} \ &\leq 1 - C\left(rac{t}{2lpha^{-1}t}
ight)^s = 1 - C(lpha/2)^s. \end{aligned}$$

As  $u \ge 0$  and u(w) = 1, we have  $|u(w) - u_{B_0}| = C(\alpha/2)^s > 0$ . From this it follows (using 'telescoping') that

$$1 \leq C \sum_{k=0}^{\infty} r_k \left( \int_{\tau B_k} g_u^p \, d\mu \right)^{1/p}.$$

▲口 ▶ ▲冊 ▶ ▲目 ▶ ▲目 ▶ ● ● ● ● ●

### Idea of the proof II

But if

$$1 \leq C \sum_{k=0}^{\infty} r_k \left( \int_{\tau B_k} g^p_u \, d\mu \right)^{1/p},$$

then, for  $\delta := (p-q)/p > 0$  there exists  $C_1 > 0$  and an index  $k_w \in \mathbb{N}$  such that

$$r_{k_w}\left(\int_{\tau B_{k_w}} g_u^p \, d\mu\right)^{1/p} \geq C_1 2^{-k_w\delta} = C t^{-\delta} r_{k_w}{}^\delta.$$

Write from now on  $B_w = B(x_w, r_w)$  instead of  $B_{k_w} = B(x_{k_w}, r_{k_w})$ .

We thus obtain for each  $w \in E$  a ball  $B_w$  such that

$$r_w^{-q}\mu(\tau B_w) \le Ct^{p-q} \int_{\tau B_w} g_u(y)^p \, d\mu. \tag{3}$$

# Idea of the proof III

With the basic '5r'-covering theorem we now obtain points  $w_i \in E$ , i = 1, 2, ..., such that the balls  $\tau B_i = B(w_i, \tau r_{w_i})$  are pairwise disjoint, but still  $E \subset \bigcup_{i=1}^{\infty} 5\tau B_i$ . Note that the radii of these covering balls are no more than  $10\tau\alpha^{-1}t$ . Using the previous estimate with doubling, the pairwise disjointness of the balls  $\tau B_i$ , and the fact that  $g_u = 0$  outside  $E_t$ , we infer

$$\begin{split} \widetilde{\mathcal{H}}^{q}_{10\tau\alpha^{-1}t}(E) &\leq \sum_{i=1}^{\infty} \mu(5\tau B_{i})(5\tau r_{w_{i}})^{-q} \leq C \sum_{i=1}^{\infty} \mu(\tau B_{i})r_{w_{i}}^{-q} \\ &\leq C \sum_{i=1}^{\infty} t^{p-q} \int_{\tau B_{i}} g_{u}(y)^{p} d\mu \\ &\leq C t^{p-q} \int_{E_{t}} g_{u}(y)^{p} d\mu, \end{split}$$

proving the Lemma.

Juha Lehrbäck (University of Jyväskylä)

# Corollary

The following result is an immediate consequence of our main Lemma and general results for sets of zero capacity:

#### Corollary

Let 1 and assume that X is a doubling metric space supportingthe <math>(1, p)-Poincaré inequality. Let  $E \subset X$  be a compact  $\alpha$ -porous set with  $0 < \widetilde{\mathcal{H}}^q(E) < \infty$ . Then, for all  $0 < t < \operatorname{diam}(E)$ , we have

$$\operatorname{cap}_p(E, E_t) \ge Ct^{q-p} \quad \text{ if } p > q,$$

and

$$\operatorname{cap}_p(E) = 0$$
 if  $p \leq q$ .

Here we only need to know that  $\widetilde{\mathcal{H}}^q(E) > 0$  implies

$$0 < \widetilde{\mathcal{H}}^q_{10\tau\alpha^{-1}\operatorname{\mathsf{diam}}(E)}(E) \leq \widetilde{\mathcal{H}}^q_{10\tau\alpha^{-1}t}(E) \text{ for all } 0 < t < \operatorname{\mathsf{diam}}(E).$$

# Another corollary

Combining the previous result and the upper bounds for neighborhood capacities in a regular space, we obtain the following version of our main result:

### Corollary

Let 1 and assume that X is a s-regular metric space supporting the <math>(1, p)-Poincaré inequality. Let  $E \subset X$  be a compact  $\alpha$ -porous set with

$$0 < \mathcal{H}^{\lambda}(E) \leq \limsup_{t \to 0} \mathcal{M}^{\lambda}_t(E) < \infty.$$

Then, for all 0 < t < diam(E), we have

$$\operatorname{cap}_p(E,E_t) pprox t^{s-\lambda-p} \quad \text{ if } p > s-\lambda,$$

and

$$\operatorname{cap}_p(E) = 0$$
 if  $p \leq s - \lambda$ .

Juha Lehrbäck (University of Jyväskylä)

3

## 'Trivial' counterexamples

Our lower bounds do not hold without the assumption that *E* is porous. Indeed, for a ball  $B \subset \mathbb{R}^n$  we have

$$\mathsf{cap}_p(B,B_t)pprox t^{n-(n-1)-p}=t^{1-p}\ll t^{-p}pprox \mathcal{H}^n_{5t}(B)t^{n-n-p}$$

as  $t \to 0$ , and, more generally, for a snowflake-type domain  $S_{\lambda} \subset \mathbb{R}^n$  with  $\dim_{\mathcal{H}}(\partial S_{\lambda}) = \lambda \in (n-1, n)$ , that

$$\operatorname{cap}_p(S,(S_\lambda)_t) pprox t^{n-\lambda-p} \ll t^{-p} pprox \mathcal{H}^n_{5t}(S_\lambda)t^{n-n-p}$$

as  $t \rightarrow 0$ .

These compact sets *B* and  $S_{\lambda}$  are *n*-regular (and of positive Lebesgue measure).

Nevertheless, this fact plays no essential role in the failure of the lower bounds, as we will see.

#### 5. An example

Juha Lehrbäck (University of	Jyväskylä) I	Neighborhood capacities
------------------------------	--------------	-------------------------

æ

Given  $\lambda \in (1, 2)$ , it is possible to construct a Cantor-type set  $E \subset \mathbb{R}^2$  so that  $\mathcal{H}^{\lambda}_{\infty}(E) > 0$  and dim $_{\mathcal{H}}(E) < 2$  (we can even take dim $_{\mathcal{H}}(E) = \lambda$ ), but for all  $1 \leq p < \infty$ 

$$\mathsf{cap}_{p}\left(\mathsf{\textit{E}},\mathsf{\textit{E}}_{t_{k}}
ight)\ll t_{k}^{2-\lambda-p}$$
 as  $k
ightarrow\infty,$ 

for a suitable sequence  $t_k \rightarrow 0$ .

Higher dimensional examples can easily be constructed along the same lines.

Notice that such a set E can not be porous.

The idea is to use a typical 'alternating' Cantor-type construction, where we have

(a) 'thick' generations of squares to guarantee the loss of porosity (or equivalently giving Assouad dimension 2 for the resulting set E),

and

(b) 'thin' generations which keep the Hausdorff dimension of E in control, in particular bounded away from 2.

# Some details I

Fix  $0 < \delta < \lambda - 1$  and  $\lambda < \tilde{\lambda} < 2$ . After running the alternating construction k times we have  $4^{n_k}$  squares of side length  $I_{n_k}$ . Let  $E^{n_k}$  denote the union of all these squares.

(a) 'thick': Choose  $t_k$  so that  $t_k^{1-\lambda+\delta} \ge 4^{n_k} I_{n_k}$ , and define  $u_k(x) = \max\{0, 1-2t_k^{-1}\operatorname{dist}(x, E^{n_k})\}$ . Then

$$\int |\nabla u_k|^p \, dx \le C 4^{n_k} I_{n_k} (t_k/2)^{1-p} \le C t_k^{1-\lambda+\delta} t_k^{1-p} \ll t_k^{2-\lambda-p}.$$

Now, we only need to guarantee, that  $u_k$  is an admissible test function for  $\operatorname{cap}_p(E, E_{t_k})$  (where E is the resulting Cantor set).

To this end, we remove from the squares in  $E^{n_k}$  'very narrow'  $(< t_k)$  strips, and continue in this way untill we have  $4^{n_k+m_k}$  squares of side length  $l_{n_k+m_k} < t_k$ , so that indeed  $E^{n_k} \subset E_{t_k}$ , and thus  $u_k \in \text{Lip}_0(E_{t_k})$ .

・ロッ ・雪 ・ ・ ヨ ・ ・ ヨ ・ ・ ヨ

# Some details II

(b) 'thin': After this we take the  $4^{n_k+m_k}$  squares and run the usual  $\lambda$ -dimensional Cantor construction on these for  $\tilde{m}_k$  steps, where  $\tilde{m}_k$  is so large that

$$4^{n_k+m_k+ ilde{m}_k}(I_{n_k+m_k+ ilde{m}_k})^{ ilde{\lambda}} < 1.$$

(This is possible because  $\lambda < \tilde{\lambda}$ ).

From this it ultimately follows, that  $\dim_{\mathcal{H}}(E) \leq \tilde{\lambda} < 2$ .

We then set  $n_{k+1} = n_k + m_k + \tilde{m}_k$ , and continue from step (a).

It is now evident, that, for all k,  $\mathcal{H}_{ct_k}^{\lambda}(E) > C_1$  for some  $C_1 > 0$ , since E is 'larger' than the standard  $\lambda$ -dimensional Cantor set. Hence it is **not** true that

$$\operatorname{\mathsf{cap}}_p(E,E_t) \geq C\mathcal{H}^\lambda_{ct}(E)t^{2-\lambda-p}$$

for all 0 < t < diam(E), showing the failure of our lower bounds.

# Hausdorff and capacity

The following result holds with very weak assumptions on the space X; we basically only need doubling.

### Proposition

Let  $1 and assume that a compact set <math>E \subset X$  satisfies  $\widetilde{\mathcal{H}}^p(E) < \infty$ . Then  $cap_p(E) = 0$ .

It is actually very easy to show that if  $\Omega \supset E$  is open, then

$$\operatorname{cap}_p(E,\Omega) \leq C\widetilde{\mathcal{H}}^p_r(E)$$

for all  $0 < r < d(E, X \setminus \Omega)/2$ , where  $C = C_d$  is the doubling constant (this holds for p = 1 as well).

The proof is just like our previous proof for the upper bounds of neighborhood capacities.

Juha Lehrbäck (University of Jyväskylä)

# The 'hard' part

It requires a bit more work to prove the following Lemma:

#### Lemma

Let  $1 and let <math display="inline">E \subset X$  be a compact set. Assume that there exists a constant  $0 < M < \infty$  such that

 $\operatorname{cap}_p(E,\Omega) < M$  for all open  $\Omega \supset E$ .

Then  $\operatorname{cap}_p(E) = 0$ .

Idea: Fix  $0 < t_0 < \operatorname{diam}(E)$ , and choose  $u_1 \in \operatorname{Lip}_0(E_{t_0})$  such that  $u_1|_E = 1$  and  $u_1$  has an upper gradient  $g_1$  with  $\int g_1^P < M$ . Write  $V_1 = \{u_1 > 1/2\} \supset E$ , let  $t_1 = \operatorname{dist}(E, X \setminus V_1)/2 > 0$ , and define  $v_1 = \min\{2u_1, 1\}$ . Then  $v_1|_{V_1} = 1$  and  $h_1 = 2g_1\chi_{X\setminus V_1}$  is an upper gradient of  $v_1$ . Moreover,  $\int h_1^P < 2^P M$ .

◆□ ▶ ◆□ ▶ ◆ □ ▶ ◆ □ ● ● ● ● ● ●

### The 'hard' part 2

Then take  $u_2 \in \operatorname{Lip}_0(E_{t_1})$  with  $u_2|_E = 1$  and  $\int g_2^p < M$  for an upper gradient  $g_2$  of  $u_2$ ; note that  $\operatorname{spt}(u_2) \subset V_1$ . Write  $V_2 = \{u_2 > 1/2\} \supset E$  and let  $t_2 = \operatorname{dist}(E, X \setminus V_2)/2 > 0$ . Define as above  $v_2 = \min\{2u_2, 1\}$ , whence  $v_2|_{V_2} = 1$  and  $h_2 = 2g_2\chi_{X\setminus V_2}$  is an upper gradient of  $v_2$  with  $\int h_2^p < 2^p M$ .

This way we find numbers  $t_0 > t_1 > \cdots > t_k > \cdots > 0$  and functions  $v_k \in \text{Lip}_0(E_{t_k})$  with upper gradients  $h_k$  satisfying: (i)  $v_k|_E = 1$ , (ii) the supports  $\text{spt}(h_k)$  are pairwise disjoint, and (iii)  $\int h_k^p < 2^p M$  for each k.

Define  $\varphi_j = j^{-1} \sum_{k=1}^{j} v_k$ . Then clearly  $\varphi_j \in \text{Lip}_0(E_{t_0})$  and  $\varphi_j|_E = 1$  for each j. Moreover,  $\psi_j = j^{-1} \sum_{k=1}^{j} h_k$  is an upper gradient of  $\varphi_j$ . Using the properties (ii) and (iii) of the functions  $h_k$  we easily calculate

$$\operatorname{cap}_p(E,E_{t_0}) \leq \int_{E_1} \psi_j^p \, d\mu = j^{-p} \sum_{k=1}^j \int_{E_1} h_k^p \, d\mu < j^{1-p} 2^p M \xrightarrow{j \to \infty} 0.$$
